The Digestive System

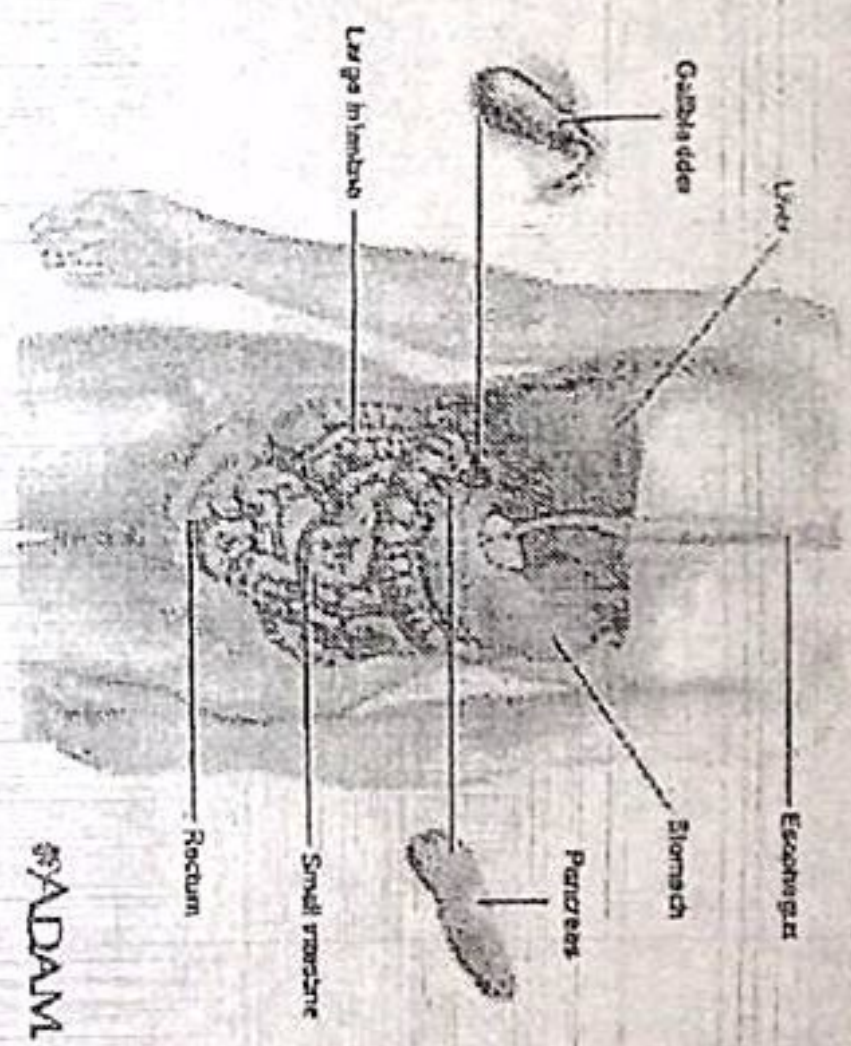

The Digestive System

Stomach Acid

Stomach Acid is a part where the food breaks down. You could face this danger, so be prepared. Stomach Acid is strong enough to disintegrate you. Be sure to try to avoid this part unless you have a suit. It turns things into soupy liquid so the it would be easier to break down in the next step, pancreas. It then goes in the small intestine and so on. Stomach Acid is a danger to avoid.

Parts of the Digestive System

The digestive system parts are important to keep the body going. The first step is the mouth. The mouth uses the teeth to tear up the food, which has nutrients, by using saliva to also tear food down. Then, it goes down the esophagus which job is to make it go to the stomach. Next, the liver adds some digestive juices and breaks it down. It goes to the stomach so it can be a soupy liquid. After that, it goes to the pancreas to be broken down by its digestive juices. It then goes to the small intestine which finishes the digestion and lets the food pass. The gall bladder stores digestive juices from the liver until it is needed for something. Last, some things go to the large intestine to remove wastes.

The Esophagus Rollercoaster

The esophagus rollercoaster is when you go down the throat and see other crushed food in the body. It is a great ride because it is worth riding a rollercoaster in someones throat. It is long ride because it isn't any ordinary rollercoaster, it's the way down for food! Be sure to try this ride because it is the way down to the liver. The food only goes down unless there is an eruption that is going to happen. If there is an eruption it would make it more enjoyable because you can go up and down every time. It is slow because it takes time for the food to go down. This is the best ride to experience in the human body!
